1 Executive Summary

This Benefit Cost Analysis is being prepared for the New Hampshire Department of Transportation (NHDOT) for improvements to Interstate 93 (I-93) in Bow and Concord, New Hampshire. The Benefit Cost Analysis (BCA) was completed in accordance with the U.S. Department of Transportation's *Benefit-Cost Analysis Guidance for Discretionary Grant Programs* (2020) for consistency with BCAs recently completed on other projects and for use by the Department in applying for additional funding opportunities, such as Infrastructure for Rebuilding America (INFRA) Discretionary Grant or other Federal grants.

This study covers a distance of approximately 2½ miles of I-93 from just south of the I-93/Interstate 89 (I-89) Interchange in Bow to just south of Exit 13 on I-93 in Concord. See Figure 1: Study Area Overview.

Figure 1: Study Area Overview

Due to population growth, development, and recreational opportunities in New Hampshire, the travel demands for I-93 between Bow and Concord have exceeded the capacity of this existing four-lane facility for several years now. Population and traffic projections for the next twenty years support the conclusion that the existing facility will be increasingly less able to function at the Levels of Service (LOS) and safety for which

it was originally designed. Decreases in the Level of Service are evident in reduced travel speeds, increased density of traffic flow, as well as in the traffic backups at some interchanges during commuting hours and summertime weekends.

During weekday peak hours as well as Friday and Sunday peak hours during summertime weekends, motorists traveling along the I-93 corridor currently experience traffic congestion and substantial travel delay. The congestion not only results in increased travel times, but also contributes to safety issues, as the limited spacing between vehicles does not afford the motorists sufficient time or space to deal with frequent and abrupt lane change maneuvers, inadequate weaving space, and sudden stops. Without substantial improvements, or dramatically reduced demand, traffic operations along this section of I-93 are expected to continue to deteriorate under future conditions as traffic volumes increase.

To the maximum extent possible, given the available data, this formal BCA is prepared in accordance with federal grant application guidelines and reflects quantifiable economic benefits. It covers primary long-term impact areas identified in the federal grant application guidelines. Table 1 shows the Executive Summary Matrix.

The improvements to the I-93 corridor in Bow & Concord results in a Benefit-Cost Ratio (BCR) of 3.25, with a BCR of 1.12 at a 7 percent discount rate, and a BCR of 1.94 at a 3 percent discount rate.

Current Status / Baseline and Problem to be Addressed	Change to Baseline or Alternatives	Type of Impacts
Continued operation and maintenance of the existing I-89 and I-93 within the project area.	Widening of I-93 to a basic six-lane interstate with auxiliary lanes as well as alterations to four interchanges	 Reduced Travel Times Reduced Fuel Use Increased Safety Avoided O&M Costs Residual Value of New Bridges Higher O&M Costs

Table 1 – Executive Summary Matrix

2 Project Description

I-93 is the principal north-south arterial highway within New Hampshire and is part of the National System of Interstate and Defense Highways. I-93 extends a total distance of 132 miles within New Hampshire, from the Massachusetts border to the northern Vermont border. The proposed project covers a distance of approximately 2½ miles from south of the I-93/Interstate Route 89 (I-89) Interchange in Bow to Exit 13 on I-93 in Concord. This segment of I-93 is also part of the Central Turnpike, commonly known as the F.E. Everett Turnpike. The project also extends along I-89 from its terminus with Route 3A (Bow Junction) approximately 4,700 feet to the west. There are four existing interchanges within the project limits. Refer to Figure 1: Study Area Overview that depicts the study area and the project limits.

The New Hampshire Department of Transportation (NHDOT) and the Federal Highway Administration (FHWA) have prepared an Environmental Assessment/Draft Section 4(f) Evaluation (EA/4(f)) for proposed improvements to the Interstate Route 93 (I-93) corridor between the Town of Bow and the City of Concord, Merrimack County, New Hampshire. The basic purpose of the I-93 Bow-Concord project is to improve transportation efficiency and reduce safety problems within this segment of highway.

I-93 in central New Hampshire was constructed in the late 1950's and early 1960's as part of the Central NH Turnpike. The need to address issues along I-93 in Bow and Concord was first identified in 1990 when the Bow-Concord Widening Project was first placed on the State's Ten-Year Plan.

Since 2012, traffic volumes on I-93 have begun to rise with 2017 having the highest all time average annual traffic. Growth in the region is expected to occur in the coming years and place a greater burden on the transportation system. With an estimated 80,000 vehicle trips per day by the year 2035, increased congestion and increased travel times are expected, unless there is a reduction in demand, implementation of management strategies, or improvements such as those proposed to this important regional travel corridor.

The Preferred Alternative for the project proposes widening I-93 from a basic four-lane interstate to a basic six-lane interstate, adding one lane in each direction within the project limits. It also includes providing auxiliary lanes in each direction on I-93 between each interchange. I-93 would therefore have eight-lanes segments between the interchanges. Improvements are also proposed at each of the interchanges to increase capacity and improve safety, mainly by reducing or eliminating weaving movements.

This Benefit-Cost Analysis (BCA) was conducted to quantify the benefits and costs of the proposed project compared to a baseline scenario, or the "No-Build" alternative. This analysis was conducted in accordance with the criteria described in the U.S. Department of Transportation's *Benefit-Cost Analysis for Discretionary Grant Programs* dated January 2020. Project benefits from the proposed project include travel time savings, fuel consumption savings, safety benefits, and avoided Operation and Maintenance (O&M)

costs associated with maintaining the existing infrastructure. There are several additional benefits of the proposed project that are difficult to quantify such as environmental protection and increased tourism economics.

3 General Assumptions

Evaluation Period

The evaluation period of benefits and costs of a project are typically for a period that includes the construction of the project and the operational period which is 20-50 years on average. For this project, the analysis period includes the project development stage which is expected to begin in 2021 with the construction programmed to begin in 2023 and be completed in 2026 with a 30-year operational period. Therefore, the BCA calculates all benefits and costs forecasted out until year 2057. As a simplifying assumption, all benefits and costs are assumed to occur at the end of each year.

No-Build Alternative

The No-Build Alternative for this BCA is the continued use and maintenance of the existing I-93 and I-89 infrastructure through Bow and Concord. Due to the critical role these roadways play in the regional transportation network, it is assumed that the roadways and bridges will need to be maintained in a state of good repair for the duration of the analysis period. Therefore, all costs associated with regular operations and maintenance costs will be included in the analysis.

There is also a "Red-List" bridge within the project area. Under the No-Build Alternative, it is assumed that this bridge will need to be reconstructed within the analysis period. This is consistent with the State of New Hampshire's Department of Transportation's practice of addressing "Red-List" bridges as a priority.

Real Discount Rate

In an effort to avoid forecasting future inflation rates and the need to grow future values for benefits and costs accordingly, all benefits and cost were valued in 2018 real dollars. Future values are deflated to reflect current values, even in the case where cost is expressed in future year values. The use of current dollar values requires the use of a real discount rate for present value discounting.

In accordance with the BCA Guidance Document, a real discount rate of 7% was used for this analysis. In addition, a 3% real discount rate was used for sensitivity analysis.

Traffic Growth Assumptions

Future year traffic volumes for the 2035 Design Year rely on growth projections developed by the Central New Hampshire Regional Planning Commission (CNHRPC). These projections are consistent with historical traffic trends within the project study area and

were developed in consultation with the municipalities within the region. In general, the 2035 future year traffic volumes are approximately 16% higher than the 2014 Base Year. This growth in traffic equates to a 0.75% increase per year. Since the traffic model does not provide traffic volume data for every year between 2021 and 2057, it was necessary to use the 0.75% growth per year to calculate traffic volumes for the years between 2021 and 2035. This growth rate was also used to predict traffic volumes beyond the year 2035 for use in the BCA.

Vehicle Delay Growth Assumptions

As previously stated, traffic volumes will continue to grow beyond the analysis year 2035. As congestion increases, it is expected that the average amount of delay that vehicles will experience will increase as well.

To determine a relationship between the growth rate of the average annual daily traffic (AADT) and the growth rate of User Delay, several analyses were performed. Traffic counts from 2014 were grown at an annual rate of 0.75% until 2054 to calculate the projected peak hour traffic volumes for the existing conditions. These peak hour volumes values from 2014 until 2054, in five-year increments, were input into Highway Capacity Software (HCS) to determine the free-flow speed and average delay speed of users through the segments of I-89 and I-93 within the limits of this project. The difference between the free-flow speed and the delay speed was used to calculate the average user delay through each segment. This delay was then multiplied by the total number of users through each segment to determine the total user delay.

This process was repeated for the AM and PM peak hours at the I-89 Exit 1 interchanges, and the I-93 Exit 12 and Exit 13 interchanges. This included merge and diverge segments, weaving segments and ramp segments. The results for these three locations were combined into a single data set which was compared to traffic volumes. A regression analysis was performed in Excel which determined that as the AADT increases annually at 0.75%, the total user delay increases annually at 2.05%. This regression analysis has an R Squared value of 0.92. R Squared measures the goodness of fit of the line of best fit to the data. The closer R Squared is to 1, the better the analysis represents the relationship between a single dependent variable and one or more independent variables

This increase was applied to both the delay experienced during the peak hours of traffic on a typical weekday as well as the delay experienced on busy tourist weekends.

Daily and Annual Traffic Assumptions

The traffic analysis performed for this project analyzed traffic operations during the AM and PM peak hours of travel on a weekday. When computing project benefits, it was assumed that these conditions occurred for five business days a week for fifty weeks a year to account for holidays. It was further assumed that traffic operations for the Build condition would be similar to the No-Build condition for all other hours of the day, i.e. there would be no changes in travel time through the corridor during non-peak hours.

Peak weekend traffic was assumed to occur between Memorial Day weekend and Columbus Day weekend as well as four other times a year for long weekends such as Veteran's Day, Thanksgiving, Martin Luther King, Jr. Day, and President's Day for a total of 24 occurrences.

Crash Data

An assessment was conducted by New Hampshire Department of Transportation for the crash occurrences in the project area from 2007 to 2016.¹ These crash occurrences were averaged over this ten-year period to estimate the number of crashes that occur each year. While it could be argued that crashes would increase at a higher rate than the volume of traffic due to additional congestion and delay, it would be difficult to estimate such an increase. Therefore, it is assumed that the number of crashes would increase in direct relation to the increase in the volume of traffic.

Service Life

Bridges are designed and expected to perform for 75 years of service life. Therefore, new bridges constructed as part of the proposed project will have several years of useful life remaining at the end of the analysis period. A residual value for these bridges has been calculated and included in this BCA to estimate the benefit of these structures at the end of the analysis period. The residual values are estimated assuming a linear depreciation over the service life of the bridge.

4 Benefits

Estimation of Benefits for Highway

The following section provides a detailed explanation and computation of the benefits associated with the proposed project within the project influence area. For the purpose of estimating benefits, it is assumed that the construction of the proposed improvements will begin in 2023 with completion in 2026. Therefore, benefits associated with reduced travel times and fewer crashes will begin to occur in 2027 as the construction is completed.

Value of Travel Time Savings (Weekday Peak Hours)

The proposed project is expected to reduce delay through the project corridor based on the traffic analysis performed by Resource System Group (RSG). This traffic analysis reviewed traffic operations in the year 2035 for both the "No-Build" and Proposed Alternatives. Table 2 shows the comparison of vehicle-hours traveled through the corridor between the No-Build and Proposed Alternatives for both the AM and PM peak hours of travel. Vehicles-hours traveled is a measurement of each vehicles travel time through

¹ New Hampshire Department of Transportation.

the corridor during the peak hour of traffic. A more detailed computation showing the vehicle-hours traveled through specific segments of the corridor is included in Appendix A.

	AM Pea	ak Hour	PM Pea	ak Hour	Reduction (Hours)		
	No-Build Proposed		No-Build	Proposed	AM Peak Hour	PM Peak Hour	
Vehicle- Hours Traveled (VHT)	949	663	873	760	286	113	
				Total	399	VHT	

Table 2 – Vehicle-Hours Traveled Comparison

The yearly travel times savings is determined by multiplying the total daily travel time savings of 399 vehicle hours by 5 business days per week and 50 business weeks per year to account for holidays. This yields a yearly travel time savings of 99,809 vehicle hours.

The value of this travel time savings is determined by applying hourly costs to the mix of vehicles which include passenger cars, both for business and personal use, as well as commercial trucks. The truck percentages were provided by RSG from a traffic count conducted in 2013 between exits 15 and 16 along the I-93 corridor and are shown in Table 3.

Table 3 – Estimated Heavy Vehicle Distribution

Analysis Period	Automobile Traffic	Truck Traffic		
Daily	94.0%	6.0%		

Based on the BCA Guidance Document, it is assumed that 88.2% of automobile travel is for personal use and the remaining 11.8% is for business use. On average, passenger vehicle occupancy is 1.48 occupants for vehicle for all trips. Commercial trucks are assumed to have an occupancy of 1 person. With this information, the overall vehicle-hours of time saved can be broken down into personal travel time, business travel time, and commercial truck time, each weighted by the number of occupants expected in each vehicle class.

These values of affected persons time are then multiplied by the corresponding value of time to arrive at the total Travel Time Savings. The values in 2018 dollars for personal automobile travel is \$15.20 per hour while the value for business automobile travel is \$27.10 per hour. For truck travel, it was assumed that 100% of the truck traffic is for business use with a value of \$29.50 per hour in 2018 dollars. These rates then applied

to the total affected volume to compute the total travel time savings on a yearly basis as shown in Appendix A. In the analysis, cumulative travel time savings are estimated to be approximately \$2,600,000 for the year 2035, which is the design year for the traffic analysis.

This 2035 value travel time savings was then adjusted to account for increases in traffic volumes as well as increases in average delay per vehicle due to the increases in traffic volumes to determine the travel time savings for the other years within the analysis period. When looking at the entire analysis period, the total value of travel time savings during the weekday peak hours of traffic is estimated to be nearly \$95,500,000.

Value of Travel Time Savings (Tourist Weekends)

The proposed project is expected to also reduce delay through the project corridor during heavy traffic on Friday evenings and Sunday evenings during the summertime and long weekend peak tourist seasons. The traffic backups on northbound I-93 during peak periods can stretch as far south as the Hooksett Toll Plaza, a distance of about ten miles from Exit 14 where the backups begin to dissipate. The traffic backup on southbound I-93 during peak periods can stretch as far north as Exit 17, a distance of about eight miles from Exit 12 where the backups begin to dissipate. While no formal traffic analysis was conducted for these events, the proposed project is expected to greatly reduce the queuing and delay that is occurring during these heavy travel times. It was assumed that the proposed project would reduce total vehicle delay by 80%.

Using the same assumptions to calculate the value of travel time savings as during the weekday peak hours of travel, cumulative travel time savings for peak weekend traffic are estimated to be approximately \$5,000,000 for the year 2035. Also, following the same methodology for accounting for increases in traffic volumes and average delay per vehicle, the total value of travel time savings during the peak weekend hours of traffic is estimated to be over \$182,000,000.

Fuel Cost Savings

The proposed project is expected to reduce the amount of fuel consumption by vehicles traveling through the project corridor during the peak hours of travel based on the traffic analysis performed by RSG. This is due to cars traveling at more constant flow with less stop and go traffic. This analysis reviewed traffic operations in the year 2035 for both the "No-Build" and Proposed Alternatives. Table 4 shows the comparison of fuel use within the corridor between the No-Build and Proposed Alternatives for both the AM and PM peak hours of travel. This table also shows the value of fuel saved per weekday using an average cost of \$2.74 for gasoline and \$3.09 for diesel fuel.

	AM Pea	ak Hour	PM Pea	ak Hour	Reduction			
	No-Build	Proposed	No-Build	Proposed	AM Peak Hour	PM Peak Hour		
Gasoline Use (Gallons)	1327	1125	1312	1278	202	33		
Gasoline Cost (\$2017)	\$3,632	\$3,080	\$3,591	\$3,500	\$552	\$91		
Diesel Use (Gallons)	450	372	450	422	78	28		
Diesel Cost (\$2017)	\$1,391	\$1,151	\$1,389	\$1,304	\$240	\$85		

The yearly fuel savings is determined by multiplying the daily fuel savings of \$968 by 5 business days per week and 50 business weeks per year to account for holidays. This yields a yearly fuel savings of nearly \$241,900 in the year 2035.

This 2035 value of fuel savings was then adjusted by 0.75% per year to determine the fuel savings for the other years within the analysis period. This adjustment is based on the assumption that the amount of fuel saved will grow at the same rate as the traffic volume. When looking at the entire analysis period, the total value of fuel savings during the weekday peak hours of traffic is estimated to be over \$7,900,000.

Crash Reduction Benefits

This project will result in minimal changes to the total Vehicle Miles Traveled (VMT) within this corridor. Therefore, there are no anticipated reductions in vehicle crashes as a result of a change in VMT. However, there are many improvements included in the proposed project that should reduce the amount of crashes through the corridor. These expected reductions in traffic are based on Crash Modification Factors (CMF) which are estimates of how individual improvements impact the rate of crashes expected. The Crash Modification Factors Clearinghouse² was consulted to determine which Crash Modification Factors best represented the intended improvements. Overall, there are seven improvements within the proposed project area that are expected to reduce crashes. Each of these areas is described in more detail below.

² Crash Modification Factor Clearinghouse"; http://www.cmfclearinghouse.org .

Weaving on I-89 Between Exit 1 and I-93

Over the 2007-2016 period, 32 total crashes were recorded within the weaving area on I-89 between Exit 1 and I-93. These crashes consisted of 18 Property Damage Only (PDO), 14 reporting injuries, and no fatal crashes. The proposed project will construct new ramps that grade separate these weaving movements, essentially removing them. There is no CMF for eliminating a weave, but the reduction in crashes would be expected to be much greater than the 20% observed when installing an auxiliary lane since the weaving maneuver is completely eliminated. Therefore, a CMF of 0.2 was used for this area.

I-89 Exit 1 Ramp Terminals

Over the 2007-2016 period, 15 total crashes were recorded at the sign-controlled intersections of the I-89 Exit 1 off ramps and South Street / Logging Hill Road. These crashes consisted of 10 PDO and 5 reporting injuries. While no fatal crashes were included in the data set, a fatal crash did occur in April of 2018 and was included in the data set. The proposed project will construct traffic signals at the ramp terminal intersections. A CMF for installing traffic signals at intersections was found to be 0.56 for all crash types and was used in this area.

Weaving on I-93 Collector Distributor Ramp at I-89

Over the 2007-2016 period, 26 total crashes were recorded within the weaving area on the I-93 Collector Distributor Ramp at the I-89 interchange. These crashes consisted of 14 PDO, 12 reporting injuries, and no fatal crashes. The proposed project will construct a new ramp to connect I-93 northbound directly to I-89 northbound which will greatly reduce the amount of traffic within the weaving movement on the Collector Distributor Ramp. There is no CMF for reducing traffic through a weave, but the reduction in crashes would be expected to be proportional to the reduction in the amount of traffic going through the weave, which is expected to be 80% in the AM and 90% in the PM. Therefore, a CMF of 0.2 was used for this area.

Weaving on I-93 Between I-89 Interchange and Exit 12

Over the 2007-2016 period, 71 total crashes were recorded within the weaving area between the I-89 interchange and Exit 12. These crashes consisted of 42 PDO, 28 reporting injuries, and 1 fatal crash. The proposed project will construct an auxiliary lane in both directions of I-93 in this area. A CMF for adding an auxiliary lane was found to be 0.77 for all crash types.

Weaving on I-93 Between Exit 12 and Exit 13

Over the 2007-2016 period, 76 total crashes were recorded within the weaving area between Exit 12 and Exit 13. These crashes consisted of 39 PDO, 37

reporting injuries, and no fatal crashes. The proposed project will construct an auxiliary lane in both directions of I-93 in this area. A CMF for adding an auxiliary lane was found to be 0.77 for all crash types.

Exit 12 Ramp Terminals

Over the 2007-2016 period, 20 total crashes were recorded at the sign-controlled intersections of the Exit 12 off ramps and NH Route 3A. These crashes consisted of 8 PDO, 12 reporting injuries, and no fatal crashes. The proposed project will combine the off ramps from two to one in each direction of the interstate and construct a roundabout at the ramp terminals. A CMF for installing roundabouts at ramp terminal intersections was found to be 0.75 for all crash types.

The BCA Guidance document includes societal costs associated with crashes involving PDO, injuries, and fatalities. These costs are \$4,400 for PDO crashes, \$451,200 for crashes involving an injury, and \$9,600,000 for fatalities. These costs were applied to the reduction in crashes anticipated by the proposed improvements to develop the value of the benefit of fewer crashes. Since the relative occurrence of crashes is a function of the volume of traffic on a given roadway, the rate of increase of crashes was compared to the increase in traffic volumes over the analysis period to determine the anticipated yearly increase in crash occurrences.

The benefit of the reduction in crashes per year was calculated based on the type of crash and summarized as a yearly savings. The cumulative crash reduction savings are estimated to be nearly \$76,200,000 through the analysis period. All data is provided in Appendix A.

Avoided Bridge Replacement & Rehabilitation Projects

As previously stated, under the No-Build alternative, it is assumed that existing bridges that are currently on the "Red-List" would need to be replaced and other bridges would need to be re-decked to keep the roadway in a state of good repair. The cost for the proposed improvement includes replacing all of these bridges. Therefore, with the implementation of the proposed project, the cost to replace the existing "Red-List" bridges and re-deck the remaining bridges would be avoided, making it a benefit for the proposed improvement. It is assumed that the one "Red-List" bridge within the project area would be replaced by 2027. Bridges that required re-decking would be done on a schedule to replace the deck approximately 40 years after being constructed. The cost to replace and re-deck existing bridges was derived by comparing the existing bridges size to recently bid work of similar nature. In total, the avoided costs of bridge replacement and rehabilitation projects would be over \$27,000,000. Table 5 provides a summary of the avoided costs.

Bridge	Priority on Current "Red- List"	Total Costs
I-89 over South St.	24	\$5,775,000
I-93 SB to I- 89 NB Ramp over Turkey River		\$3,100,000
I-93 SB over B&M Railroad		\$4,600,000
I-93 NB over B&M Railroad		\$5,300,000
I-93 SB over Hall St.		\$4,200,000
I-93 NB over Hall St.		\$4,200,000

Table 5 – Avoided Bridge Replacement & Rehabilitation Projects

Emissions Reductions Benefits

Due to increases in travel efficiency, the proposed project would have a benefit associated with fewer emissions of sulfur dioxide, nitrogen oxides, fine particulate matter, and volatile organic compounds. While a value could be calculated for this benefit, it is assumed that it would not be a significant amount due to the limited reduction in emissions expected under the proposed project.

Non-Monetized Benefits

In addition to the quantifiable monetized benefits above, the project also generates some benefits that are tangible, but difficult to quantify. Below is a description of some of these benefits.

Economic Competitiveness

Interstate 89 and Interstate 93 are the two main interstate highways serving Concord with links to the State of Vermont, White Mountains and New Hampshire's seacoast. Interstate 93 through Concord connects with Interstates 89 and 393 continuing down to Bow and serves as a vital link to commuters and a wealth of jobs in northern Massachusetts. One of the largest industries in NH is tourism and this project will provide a safer, more efficient connection between these attractions and their users. Therefore, the proposed improvements will maintain long-term efficiency of the system, travel time reliability for all users, and cost competitiveness of goods. The benefits to economic competitive focusing on tourism and are further detailed in Applied Economic Research's *Estimate Tourism Benefits* report dated October 29, 2018 which is included in Appendix B.

The Manchester-Boston Regional Airport located 23 miles south of Bow & Concord is the state's largest airport. The Airport is a key transportation facility serving NH and one of the largest economic drivers supporting NH's economy with nearly \$23.7 Million generated in tax revenue for the state of New Hampshire in 2015. It also serves as the central air cargo hub for UPS and FedEx carriers serving northern New England.³ Many businesses in the region rely on this cargo hub for the transportation of goods or persons, including educational and healthcare institutions, large retailers, and financial firms. The proposed improvements will provide a safer, more efficient connection between New Hampshire, Massachusetts, and the region, which is key to maintaining the economic stability and growth of this region.

Quality of Life

Constructing the proposed project will result in improved operations along the corridor and improve safety which will have positive impacts on travel through this area for both business and personal endeavors including work, shopping, school, medical treatment and recreational activities. The proposed improvements will continue to provide safe & efficient access to these facilities ensuring that people are able to continue to obtain excellent medical care.

Environmental Sustainability

Until recently, stormwater runoff along I-93 within the project limits discharged into the adjacent waterbodies with little or no treatment. Recent projects to address Red List bridges in the corridor installed several gravel wetlands to treat portions of the runoff. An additional nine potential treatment areas have been identified as part of the proposed project to provide measurable benefit to the water quality of the Merrimack River.

5 Costs

Capital Expenditures

The total capital expenditures for the proposed project include preliminary engineering and permitting, right-of-way acquisition, mitigation, utility relocation and construction. The estimated cost to construct the proposed project is \$126.4 M. These costs have been adjusted to be current year 2018 values. A detailed cost estimate is shown in Appendix A.

³ 2015 NH State Airport System Plan, New Hampshire Department of Transportation. Individual Airport Summary Report Manchester-Boston Regional Airport, 2015.

Operation and Maintenance Costs

Once constructed, the proposed project will incur future roadway and bridge maintenance costs in order to maintain a state of good repair that are in addition to future roadway and bridge maintenance costs that would occur under the No Build alternative. These additional costs will consist of annual cleaning of the bridge decks and superstructures. Additional pavement preservation costs would occur every 10 years after the project is complete due to the additional pavement area resulting from the proposed project. These additional maintenance and operation costs have been included in the BCA as negative benefits in accordance with the BCA Guidance document.

Similar to the avoided bridge replacement and rehabilitation costs, there is also a pavement preservation project that would occur under the No Build alternative but would not be needed under the proposed project. This avoided pavement preservation is expected to cost approximately \$5,000,000 and has been included as a benefit under the BCA.

Residual Value of New and Replaced Bridges

Another benefit of the proposed project would be the residual value of new bridges and existing bridges that are planned to be replaced. As these bridges would be constructed with a 75-year design life, they would have residual value remaining at the end of the analysis period. The total value of the bridges that are either a new bridge or an existing bridge that will be replaced in current 2018 dollars is over \$32,800,000. As these bridges would have 45 years remaining of useful life at the end of the analysis period, the residual value is estimated at nearly \$19,700,000.

6 Comparing Benefits to Costs

A summary of the benefits and costs quantified for the proposed project are summarized in Table 6 below. Benefits and costs are expressed in real dollars (2018) as well as values that have been discounted at 3% and 7% over the analysis period. The comparison of the benefits to the costs are presented in terms of Net Present Value (NPV) as well as a Benefit to Cost Ratio (BCR).

Criteria	Real Dollars (2018)	3% Discount Rate	7% Discount Rate
Travel Time Savings (Weekday)	\$95,507,808	\$46,377,346	\$20,229,928
Travel Time Savings (Peak Weekends)	\$182,402,171	\$88,572,114	\$38,635,404
Fuel Savings	\$7,918,791	\$3,963,123	\$1,793,388
Crash Reductions	\$76,243,628	\$38,129,216	\$17,248,005
Avoided Bridge Projects	\$27,175,000	\$18,317,899	\$11,187,872
Residual Value of Bridges	\$19,700,000	\$6,220,345	\$1,407,664

Notes

1. Based on Conceptual Cost Estimate (\$2018) dated July 2018

2. Bridge Maintenance cost assumed to be yearly cleaning. Additional work such as membrane and deck replacement would occur outside the scope of this BCA timeline

3 Highway Maintenance includes additional pavement preservation projects at 10-year interval after opening

5. There is no CMF for reducing traffic through a weave, but the reduction in crashes would be expected to be proportional to the reduction in the amount of traffic going through the weave, which is expected to be 80% in the AM and 90% in the PM. Will use a CMF of 0.20.

TRAVEL AND TOURISM BENEFITS :

Synopsis of Findings

This analysis was completed by Applied Economic Research. Its purpose is to identify the significance of the tourist/visitor market and the tourist/visitor benefits of the proposed improvements within the Bow-Concord I-93 study area

The conclusions of this analysis are:

- Travel and Tourism is second only to manufacturing in economic importance in the State;
- Travel and tourism visits support nearly 70,000 jobs and account for over \$5 billion in spending;
- Visitors and second home owners are a major revenue source for the State and local governments;
- The Study Area Corridor is the most important infrastructure serving in the State's tourist/visitor market, carrying an estimated 5 million visitor vehicles per year, despite noticeable congestion during peak visitor weekend periods;
- The current delays are a nuisance to visitors. It is reasonable to presume that current congestion, which results in several miles of backed-up traffic on peak visitor weekends, is probably deterring some visitation and deflecting visitation to other destinations, such as Vermont.
- If the improvements are not undertaken, the current delays are likely to increase and probably become a more significant deterrent to visitors in the coming years;
- Over the long term, the proposed improvements provide protection against the negative impact of future rising peak hour volumes, which would probably result in reduced visitation.
- In the short term, the improvements will reduce the annoyance that current delays generate for the tourist/visitor market. Doing so could increase visitation.

TRAVEL AND TOURISM BENEFITS

Travel and tourism are the second largest industry in the State, second only to manufacturing as a source of economic vitality. A healthy tourism sector is important to the State and its municipalities.

Economic Indicators

The State's tourism sector is multi-faceted, including the strong three-season elements of (1) summer hiking, boating, swimming etc. in the Seacoast, White Mountains and Lakes Region, (2) an internationally prominent Fall foliage season, and (3) winter activities including snowmobiling and(4) cross-country and downhill skiing (18 primary downhill ski areas). It has proven to be less volatile than other sectors of the State's economy, providing economic support and growth in both good times and bad.

According to the State's 2015 Travel Barometer compiled by Plymouth State University (a copy of which is appended to this report):

- Travel and tourism accounted for 67,000 jobs in the State—providing employment for nearly 10% of the State's employed residents;
- The State attracted an estimated 39 million visitor trips;
- Rooms and Meals spending, underlying the State's Rooms and Meals tax totaled \$3.1 billion, of which \$2 billion arose from visitor spending;
- Total visitor spending was over \$5.3 billion;

An additional facet of the industry in New Hampshire is the prominent inventory of second homes in the State, particularly in Belknap, Carroll, Coos and Grafton counties, which have a collective inventory of over 47,000 second homes, accounting for 31 percent of their total housing inventory:

	Total Units	Seasonal Units	Seasonal Percent of Total
			%
Belknap County	37,715	11,327	30%
Carroll County	40,287	17,041	42%
Grafton County	51,773	13,414	26%
Coos County	21,277	5,481	26%
Served by Study Area	151,052	47,263	31%
New Hampshire	620,729	66,969	11%

Seasonal Units in Visitor Counties Served by Study Area

\tourism impacts

These second homes carry above average assessed values and generate relatively low service demands on their host communities, providing critical support for the funding of municipal services and schools.

The State relies on tourism spending as a major revenue source. The State's Rooms and Meals tax levied at 9%, generated \$330 in revenues in Fiscal Year 2018—13% of total General Fund/Education revenues and a 17% increase since Fiscal Year 2015. Essentially all of the lodging receipts and (according to Plymouth State University) half of the meals receipts are generated by travel and tourism spending.

Recognizing the importance of the industry, the State spends \$#### annually marketing and promoting tourism.

Study Area Influence on Tourism

Interstate 93 provides a critical link between (1) the State's major visitor destinations (the White Mountains and Lakes region) and (2) the affluent primary market served by the State's tourism industry (southern New Hampshire and eastern Massachusetts). The Plymouth State University Travel Barometers analysis examined average Saturday traffic counts (which highlight visitation volumes) among 12 traffic counters approaching or within the State's travel destinations with the following results:

Indicator	Vehicle Counts	% from prior year
US 3 Groveton	2,834	1.4%
US 2 Jefferson	4,492	3.0%
US 302 Bartlett	3,737	4.3%
I-93 Lincoln	10,663	3.5%
NH 12 Claremont	8,453	-1.3%
I-89 Sutton	18,558	1.1%
NH 16 Ossipee	12,602	1.5%
NH 11 Alton	6,363	1.9%
NH 101 Temple	7,583	0.6%
NH 9 Chesterfield	11,406	-0.2%
I-93 S Concord	69,236	0.8%
NH 101 Exeter	38,281	2.5%
Total Traffic Counts	194,206	1.4%

Interstate 93 traffic counts within the Study Area (I-93 S Concord) are well above any other counter compiled by their analysis. In effect, Interstate 93, including the Study Area in particular, is the principal corridor through which tourist visitors pass on their way to destinations in the Lakes and Mountain regions. The study area incorporates travelers arriving from points south via Interstate 293 and the NH Turnpike, from the east via Route 101 and 4, and from the west via Interstate 89.

Estimated Visitor Traffic Volumes

There is no inventory of visitor traffic flows through the corridor. It is impractical to collect such data. The corridor carries conventional traffic (commuters, shoppers, general business activity, etc.) as well as tourism traffic. It is known, however that a substantial portion (but not all) of tourist/visitor traffic occurs on weekends.

There is a traffic counter between Exits 12 and 13 within the corridor. AER has compiled weekend (Friday, Saturday and Sunday) traffic volumes at this counter for the 12 months beginning March 2017 through February 2018. A copy of the monthly figures is in the Addendum to this report with the following results:

The data reveals a strong seasonality to the flow volumes, most of which can be attributed to tourism/visitors. The counter shows about 800,000 vehicles pass through the counter in March, April and November, months that are not prime visitor/tourist seasons. In contrast, about one million vehicles pass over the counter monthly in May-October, the prime summer and foliage visitor months.¹

These volumes, which peak at about 100,000 vehicles per weekend day in the summer, exceed the capacity of the study area. There are, therefore, substantial back-ups and delays on prime visitor weekends.

¹ January 2018 was atypical for tourism due to a lack of snow.

Estimating tourist-visitor volumes is complicated by:

- During the prime visitor months weekend trips also include non-visitor trips, particularly daytime Friday traffic;
- The non-prime visitor months include primarily no-visitor traffic, but also include some visitor traffic;
- Visitors also use the corridor during weekdays, although less frequently than on weekends.

These complications and the lack of specific data on how many visitors passing through the corridor mean that this analysis can only be presented as an order-of-magnitude estimate.

AER's estimate begins with April volumes. April does include some tourism/visitation, but lies outside the prime winter, summer, and foliage tourist/visitor seasons. As such, it illuminates the base weekend traffic volume, apart from tourist/visitor volumes, experienced. Monthly variations from the base are generally indicative of the estimated volume of tourism/visitor traffic volumes.

It is appropriate to allow for some visitor traffic in the April counts. Examining the universe of the traffic data, included in the Addendum to this report, suggests that about one-third of the April weekend traffic of 809,057 is attributable to tourist-visitor flows, meaning that two-thirds of the April volume is non-visitor traffic. The resulting base volume, of 542,068, is AER's estimate of the volume of weekend traffic that could be expected in the absence of visitor traffic.

April Weekend Volume	809,057
Less: Allowance for Visitor Volume-%	-33%
Estimated April Visitor Volume	(266,989)
April Base Volume Non Visitor	542,068

The next step is to contrast total weekend traffic counts by month to this figure and compute the variance between the actual total monthly traffic and the 542,068 estimated non-visitor monthly flows, per the figures and chart on the following page.

	Weekend Count	Less: Non- Visitor Base Volume	Equals Estimated Visitor Volume	Visitor Volume as a % of Total
March	826,010	(542,068)	283,942	34%
April	809,057	(542,068)	266,989	33%
May	936,865	(542,068)	394,797	42%
June	999,109	(542,068)	457.041	46%
July	1,070,780	(542,068)	528,712	49%
August	1,046,683	(542,068)	504.615	48%
Sept	1,003,578	(542,068)	461.510	46%
Oct	985,720	(542,068)	443,652	45%
Nov	840,208	(542,068)	298,140	35%
Dec	963,867	(542,068)	421,799	44%
Jan	796,735	(542,068)	254,667	32%
Feb	846,539	(542,068)	304,471	36%
	11,125,151	(542,068)	4,620,333	42%

The estimate is that visitors account for 4.6 million trips or 42% of weekend traffic volumes in the corridor over the course of a year. In addition, some visitor traffic is experienced Monday-Thursday, possibly resulting in a 10% increase over the course of a year. Recognizing that these are order-of-magnitude estimates, the total annual visitor vehicle count is estimated to be on the order of about 5 million vehicles per year.

Estimated Benefits

The data in the preceding sections of this report indicate that the Study Area carries an estimated five million tourist/visitor vehicles per year. An interview with the head of the State's tourism division indicated that even with existing congestion during peak weekend tourist flows, the corridor is a vital element of the State's tourism industry.

Traffic delays are common among comparable visitor corridors, including I-95 along the Seacoast and approach to Cape Cod. Visitors are willing to tolerate delays in accessing the State's recreational resources. While it is not possible to quantify the impact of current congestion, it is reasonable to expect that the existing congestion at peak visitor times is discouraging some visitation or deflecting visitation to other destinations—Vermont, for example.

Over time, if no improvements are completed, visitor visits are likely to rise, increasing the delays experienced due to peak hour congestion and probably reducing the State's tourism market penetration.

Conclusion

The conclusions of this analysis are:

- Travel and Tourism is second only to manufacturing in economic importance in the State;
- Travel and tourism visits support nearly 70,000 jobs and account for over \$5 billion in spending;
- Visitors and second home owners are a major revenue source for the State and local governments;
- The Study Area Corridor is the most important infrastructure serving in the State's tourist/visitor market, carrying an estimated 5 million visitor vehicles per year, despite noticeable congestion during peak visitor weekend periods;
- The current delays are a nuisance to visitors. It is reasonable to presume that current congestion, which results in several miles of backed-up traffic on peak visitor weekends, is probably deterring some visitation and deflecting visitation to other destinations, such as Vermont.
- If the improvements are not undertaken, the current delays are likely to increase and probably become a more significant deterrent to visitors in the coming years;
- Over the long term, the proposed improvements provide protection against the negative impact of future rising peak hour volumes, which would probably result in reduced visitation.
- In the short term, the improvements will reduce the annoyance that current delays generate for the tourist/visitor market. Doing so could increase visitation.

ADDENDUM

Plymouth State University Travel Barometers

Overall Performance

The indicators used in the "travel barometer" for New Hampshire show that fiscal year 2015 was a positive period for the State's travel sector when compared with fiscal year 2014. More travelers visited the state and they spent more during fiscal year 2015 than during 2014. In fact, it was the best year in the last two decades. Real spending at lodgings after inflationadjustment was a record high since the INHS started tracking this data in 1988. The share of day travelers in total increased slightly.

Indicator

Estimated Visitor Counts and Spending (in millions)

Visitor counts and spending are estimated by the INHS, and are indicative of the health of all tourism industries in the state collectively, which include not only lodging and restaurants, but also arts, entertainment, and recreation, and part of retail and transportation.

Indicator	Value	prior year
Visitor Trips	38.40	5.1%
Visitor Days	60.16	5.2%
Visitor Spending	\$5,361	8.1%
Visitor Spending		
per Day	\$89	2.8%
Retail Spending	\$1,429	6.0%

Value

Indicator	Sales	% from	
R&M	\$3,143	7.5%	
Restaurants	\$1,959	8.0%	
Rooms	\$529	7.8%	
Combination Other Food	\$107	7.7%	
Service	\$547	5.4%	
R&M_T	\$2,081	10.7%	
CPI	237	0.7%	

Rooms and Meals Sales (in millions)

Rooms and meals sales are the baseline measurement of the tourism sector, which provides the basis of other tourism indicators such as traveler counts and spending. It's the official count of sales as reported by the NHDRA. Nearly all of lodging (Rooms) and meals at hotels and resorts (Combination) are paid by travelers, while only about half of the restaurant meals are estimated to be paid by travelers.

Employment in Tourism Sector (in thousands)

The number of employed residents in the state is from the Household survey, and is indicative of the health of the state's overall economy. The numbers of jobs in tourism industries are from the Establishment Survey, and collectively indicate the health of the tourism sector. It is the only current tourism indicator that is publicly available and comparable across different states in the country.

Total Traffic Counts	194,206	1.4%

Saturday Traffic Counts

The vehicle traffic counts should be reflective of changes in the volume of traveler counts. The vehicle counts are collected on Saturdays, in order to reduce the volume of commuter traffic in the data. Furthermore, 12 recorders are selected nearby major travel destinations to reflect traveler traffic in each of the seven travel regions in the State.

Spread	6,531	5.6%

<u>Comparison with New England and U.S.</u> (in thousands)

The number of jobs estimates in the leisure and hospitality sector from the U.S. Bureau of Labor Statistics is the only tourism indicator that is comparable across states in the country. Therefore, it provides a glance of the performance of the state's tourism sector relative to other states in New England and the rest of the country.

Indicator	Days	% from prior year
Days with Precipitation	138	2.2%
Days with Snowcover	61	-1.6%

Leading Indicators

Increases in the leading indicators may be indicative of more businesses for the tourism sector in the near future, while decreases may mean the opposite. An exception is the gas price. A substantial increase in gas prices may discourage traveling.

*The percent change in Visitnh.gov Total Sessions was not reported because the numbers are not comparable between FY12 and FY13. The software used to track the online traffic was changed at the beginning of the FY13, and so was the way in which the traffic was measured.

NEW HAMPSHIRE'S TOURISM SECTOR, RELATIVE TO OTHER STATES

According to the national visitor survey information obtained from TNS Global Market Research, the State makes up 0.74% of the domestic traveler market. The program excludes foreign travelers. Out of 74,513 visits in the United States reported by the survey respondents, 552 visited New Hampshire during calendar year 2014. This ranks the state 39th out of 50 states plus Washington D.C. California and Florida were the top destinations in the country in that order. However, this ranking doesn't take into account the size of the states. In terms of the number of visits per 1,000 residents, New Hampshire ranks 7th, marking 0.42 reported visits per 1,000 residents, compared to 0.17 reported visits per 1,000 residents. The state's travel industry has performed well since 2010. The State's domestic market share increased to 0.74% in 2014 from 0.61% in 2010. Its ranking improved to 39th from 42nd during the same period. The number of visits per 1,000 residents in 2010.

New Hampshire's Travel Industry Compared to Other States

A-4

DEFINITION OF THE INDICATORS

Visitor trips and days

A traveler visiting a travel destination in New Hampshire is counted as one visitor trip, whether the traveler is New Hampshire resident or not. If the travel lasts three days, then the trip is counted as three visitor days. Visitor counts are estimated by the INHS based on a multitude of tourism indicators as well as visitor surveys conducted by a third party research firm, and benchmarked to sales and employment data of the tourism industries obtained from the U.S. Census Bureau and the U.S. Bureau of Economic Analysis.

Visitor and retail spending

Total visitor spending represents direct purchases made by travelers to New Hampshire, which includes sales of lodging, restaurant meals, entertainment, amenities, and transportation. Visitor spending is estimated by the INHS based on a multitude of tourism indicators as well as visitor surveys conducted by a third party research firm, and benchmarked to sales and employment data of the tourism industries obtained from the U.S. Census Bureau and the U.S. Bureau of Economic Analysis.

Rooms and Meals Tax Revenues

Rooms and meals tax revenues data is considered as one of the most important indicators for the tourism sector, the one that provides the basis for estimating other tourism indicators. There are two major reasons for this. First, it is an official amount, not an estimate, of tax collected on sales of lodging and meals, as reported by the New Hampshire Department of Revenue. Secondly, the lodging and restaurant industry is a major player in the tourism sector in terms of employment and sales.

Employment

The report includes two different sources of the U.S. Bureau of Labor Statistics employment data – the household survey and the establishment survey. The number of employed residents is estimated from the household survey, and is indicative of the state-wide labor market. On the other hand, the number of jobs in tourism industries is estimated from the establishment survey, and is reflective of the health of the tourism sector.

Gasoline Prices

¢

New England Regular Conventional Retail Gasoline Prices (Dollars per Gallon) are obtained from

the U.S. Energy Information Administration. A substantial increase in gasoline prices may discourage traveling.

Saturday Traffic Counts

The New Hampshire Department of Transportation collects vehicle traffic counts via 60 plus automatic recorders placed throughout the state. The average Saturday vehicle traffic counts are used, in order to reduce the volume of *commuter traffic* in the data. Furthermore, 12 recorders are selected nearly major travel destinations to reflect *traveler traffic* in each of the seven travel regions in the State.

Hotel Occupancy Rate

The monthly values of the hotel occupancy rate are obtained from the Smith Travel Research once a year. Thus, seasonal values until the next release of the data are estimated by the INHS.

Airline Passengers

It measures the number of passengers enplaning at the Manchester airport. It's one of the indicators for the business travel volume.

Vehicle Rentals

It measures spending on motor vehicle rentals subject to the Rooms and Meals Tax. It's one of the indicators for the business travel volume.

Attractions Attendance

It counts attendance at nine seasonal attractions during summer in the state.

Requests for DTTD Guidebooks

It counts the number of requests for DTTD <u>Guidebooks</u>. It's considered as one of the leading indicators for the tourism sector.

Visitnh.gov Total Sessions

It counts the number of total sessions at www.visitnh.gov. It's considered as one of the leading

A - 8

indicators for the tourism sector.

The Canadian Dollar

The value of the Canadian dollar relative to the United States' dollar is an indicator of present and future travel by the Canadian tourist in New Hampshire. Canada is the most important source of foreign tourists in the state. An increase in the value of Canadian dollar per the U.S. dollar makes traveling to the United States more affordable for Canadians in their currency, which may lead to an increase in the number of Canadian travelers to New Hampshire, other things equal. Thus, it is considered as a leading indicator for the state's tourism sector.

The British Pound

Great Britain is the largest source of foreign travelers in New Hampshire after Canada. An increase in the value of British pound per the U.S. dollar makes traveling to the United States more affordable for the British in their currency, which may lead to an increase in the number of British travelers to New Hampshire, other things equal. Thus, it is considered as a leading indicator for the state's tourism sector.

Interest Rate Spread

The interest rate spread, the 10 year Treasury less the Federal Funds, is considered one of the best leading indicators for the national economy. The indicator is the sum of all the past values plus the spread in the current period. Therefore, it decreases when the current spread is negative (the 10 year T rate is lower than the Fed Funds Rate), which is indicative of an impending recession. January 1960 is the base period; the interest rate spread is zero in January 1960.

Weather

Weather is a critical factor determining the traveler volume. More rainy days during summer lead to fewer travelers to the state, while more snowy days during winter lead to more travelers.
